METHOD AND SYSTEM FOR PREVENTING CLATHRATE HYDRATE 1 2 BLOCKAGE FORMATION IN FLOW LINES BY ENHANCING WATER CUT 3 4 TECHNICAL FIELD 5 6 The present invention relates to preventing the formation of clathrate hydrate 7 blockages in flow lines or conduits carrying hydrocarbons. 8 9 BACKGROUND OF THE INVENTION 10 Clathrate hydrate plug formation in oil and gas pipelines is a severe problem for 11 12 the petroleum industry. When water is produced along with gas, oil, or mixtures 13 of both, under the right pressure and temperature conditions, there is a 14 potential to form a solid hydrate phase. Pressure-temperature conditions 15 favorable for hydrate formation are commonly encountered during the winter in 16 fields onshore and in shallow water depths offshore, and regularly in deepwater 17 (>1,500 feet water depth) fields offshore. As a rule of thumb, at a seafloor 18 temperature of about 40°F for water depths greater than 3,000 feet, hydrates 19 can form in a typical natural gas pipeline at pressures as low as 250 psi. As 20 solid hydrates form, the hydrates can deposit on the pipe walls or agglomerate 21 into larger solid masses creating obstructions to flow. 22 23 Technologies currently used to prevent hydrate blockage formation include 24 dehydration, heat and/or pressure management or chemical injection with 25 thermodynamic or low dosage hydrate inhibitors (LDHI). Dehydration is simply 26 removing most of the water from the hydrocarbon stream so that too little is left 27 to form hydrate blockages. Temperature or pressure control is used to operate 28 a system outside of conditions that can promote hydrate formation. The 29 addition of thermodynamic inhibitors (typically alcohols, glycols or salts) 30 produces an anti-freeze like effect that shifts the hydrate phase equilibrium 31 condition to lower temperatures at a given pressure so that a system may be

operated safely outside the hydrate stability region. LDHI act in one of two

ways: 1) as a kinetic inhibitor, or 2) as an anti-agglomerant. Kinetic LDHIs

32

1	merely slow the hydrate formation rate so that formation of a solid blockage is
2	retarded during the residence time of the fluids in the pipeline. Anti-
3	agglomerant LDHIs allow the hydrates to form, but keep the hydrate particles
4	dispersed in a liquid hydrocarbon phase. Anti-agglomerant LDHIs are also
5	known to have limitations on the water cut in which the chemicals can work.
6	They are usually recommended for application for water cuts of less than 50%.
7	
8	Each of these solutions for hydrate prevention can work, but all require
9	significant capital or operating expense. The thermal and dehydration options
10	are capital intensive, the thermodynamic inhibitor options are both capital and
11	operationally intensive, and the LDHI option is operationally intensive. LDHIs
12	also have additional risk associated with their application due to the relative
13	immaturity of the technology. Additionally, discharge water quality (toxicity) and
14	crude quality (methanol content for example) issues can be a concern when
15	using both thermodynamic inhibitors and LDHIs. There is also a general
16	concern in the industry that as remote deepwater fields mature, water cuts may
17	become high to the point where chemical injection for hydrate inhibition may
18	offer considerable challenges – either due to the sheer volumes of
19	thermodynamic inhibitor required or due to limitations on LDHI performance as
20	mentioned above. Therefore, the issue of a cost-effective and reliable hydrate
21	inhibition strategy for fields with high water cuts is a major challenge facing the
22	industry.
23	
24	There are additional flow assurance issues commonly found with low-
25	temperature high pressure flow in flow lines. In cases where there is water in
26	an oil emulsion, such an emulsion can have high viscosity leading to problems
27	associated with excessive pressure drop. The present invention, to be
28	described hereafter, addresses the challenges described above.
29	
30	SUMMARY OF THE INVENTION
31	
32	The present invention includes a method for inhibiting hydrate formation
33	blockage in flow lines used to transport hydrocarbon containing fluids. Water

1 is added to a hydrocarbon containing fluid to produce a water cut enhanced 2 hydrocarbon containing fluid. The water cut enhanced hydrocarbon 3 containing fluid is then transported by a flow line. Hydrate formation blockage 4 is inhibited from forming within the flow line by the addition of the water which 5 tends to lower the hydrate phase equilibrium temperature for a given pressure 6 of the hydrocarbon containing fluid and flow velocity. 7 8 Preferably, the resulting water cut enhanced hydrocarbon containing fluid is 9 water continuous. Sufficient water may be added such that the hydrocarbon 10 containing fluid is inverted from a water in oil emulsion to a water continuous 11 emulsion state thereby decreasing emulsion viscosity and reducing pressure 12 drop in the flow line. 13 14 Sufficient water may be added such that the water cut of the water cut 15 enhanced hydrocarbon containing fluid is at least 50%, and possibly even 16 75% or 85%. The hydrate thermal equilibrium temperature of the water cut 17 enhanced hydrocarbon containing fluid may be lowered 2.5°F, 5.0°F, or even 18 10°F as compared to the original hydrocarbon containing fluid. 19 20 Further, sufficient water may be added to the original hydrocarbon containing 21 fluid such that there is an excess of the water phase relative to the hydrocarbon 22 phase such that hydrate formation is self limiting. This occurs when the 23 hydrocarbon hydrate forming components are exhausted through hydrate 24 formation and a flowing slurry of hydrates, hydrocarbons and water results. 25 26 Salt may be added to increase the salinity of the water cut enhanced 27 hydrocarbon containing fluid. The weight % of salt in the water cut enhanced 28 hydrocarbon containing fluid may be 5%, 10% or even 15% or higher. 29 30 A system for preventing the formation of hydrate blockage in flow lines is also 31 provided. The system includes a flow line for transporting a hydrocarbon 32 containing fluid and a water injection conduit fluidly connected to the flow line 33 to add water to the flow line to increase the water cut of the fluid flowing

1 through the flow line. The flow line should be connected to a hydrocarbon 2 source and the water injection conduit fluidly connected to a water source. 3 The system may be operable in an environment sufficiently cool such that 4 hydrate blockage might form absent the addition of water to the hydrocarbon 5 containing fluid from the water injection conduit. The hydrocarbon source 6 may be a well bore from which hydrocarbons are produced. The water source 7 may sea water, a sub sea water well or a water storage tank mounted on an 8 offshore platform. Alternatively, the system may be used on land where 9 hydrocarbon containing fluids are to be transported in flow lines and the flow 10 lines are exposed to cold temperatures. 11 12 The system may further include a water separator to separate water from 13 hydrocarbons received from the flow line. The flow line, water separator and 14 water injection conduit may cooperate to form a partially closed loop wherein 15 water from the flow line may be separated by the water separator and 16 delivered back to the water injection conduit to be reinjected into the flow line 17 to enhance the water cut of the hydrocarbon containing fluid. 18 19 It is an object of the present invention to provide a method and system to 20 address multiple flow assurance issues (hydrate inhibition, emulsion 21 viscosity/stability, system thermal performance, and system hydraulic 22 performance) through a simple, cost-effective, and environmentally friendly 23 strategy. 24 25 It is another object to provide a method for multiphase production of crude oil 26 and natural gas wherein hydrocarbon containing fluids are transported through 27 a flow line at unconventionally high water cuts to thereby reduce hydrate 28 blockages in the flow line relative to using hydrocarbon containing fluids having 29 a lower water cut.

1	BRIEF DESCRIPTION OF THE DRAWINGS
2	
3	These and other objects, features and advantages of the present invention
4	will become better understood with regard to the following description,
5	pending claims and accompanying drawings where:
6	
7	FIG. 1 is a graph showing the thermodynamic effect of water cut and brine
8	salinity on the hydrate stability region of a heavy oil;
9	
10	FIG. 2 is a graph showing the general change in viscosity of emulsions as a
11	function of water cut;
12	
13	FIG. 3 is a first embodiment of a hydrate blockage inhibiting system which
14	includes a water injection conduit which injects water and/or salt into a sub sea
15	wellhead tree to enhance the water cut of a hydrocarbon containing fluid carried
16	by a flow line to a floating platform in a sea;
17	
18	FIG. 4 is a second embodiment of a hydrate blockage inhibiting system which
19	includes water injection into a sub sea manifold;
20	•
21	FIG. 5 is a third embodiment of a hydrate blockage inhibiting system which
22	includes water injection at a riser base;
23	moladee water injection at a ricer base,
24 25	FIG. 6 is a fourth embodiment of a hydrate blockage inhibiting system using a
25	submersible pump to inject sea water into a wellhead tree;
26	
27	FIG. 7 is a fifth embodiment of a hydrate blockage inhibiting system using a
28	submersible pump to inject sea water into a sub sea manifold; and

FIG. 8 is a sixth embodiment of a hydrate blockage inhibiting system which injects water from a sub sea well into a production fluid collected from a fresh water sub sea well.

BEST MODE(S) FOR CARRYING OUT THE INVENTION

The present invention is counterintuitive and surprising in that it calls for adding excess water to a hydrocarbon containing fluid to inhibit hydrate blockage formations in flow lines of a system. Conventional wisdom is to remove water and/or add chemical hydrate inhibitors. This process of purposely adding water, which is abundantly available in offshore operations, may be a cost-effective, reliable hydrate blockage inhibition strategy with several potential additional side benefits. The present invention may also be used on land as well to inhibit hydrate formation blockages where hydrocarbon containing fluids are transported along a flow line exposed to cold temperatures.

This invention applies to multiphase flow systems where formation of hydrate plugs or other significant hydrate obstructions in flow lines are a concern. Ideally, water, and possibly salt or brine, is added to a hydrocarbon containing fluid such that a water continuous phase is present (high water cut). The addition of the water and salt to the hydrocarbon containing fluid ideally addresses multiple flow assurance issues (hydrate inhibition, emulsion viscosity/stability, system thermal performance, and system hydraulic performance) through a simple, cost-effective, and environmentally friendly strategy.

Following this strategy, injection of water could be used to operate systems in a water continuous emulsion state, thereby decreasing emulsion viscosity and reducing pressure drops in pipe lines or flow lines. This could be beneficial especially for heavy oils that may be prone to forming high viscosity water in oil emulsions at cold sub sea conditions. Further, if a high salinity brine is injected instead of fresh water, separation problems topside due to emulsions could be

1 potentially alleviated, or at least reduced, since salt can have an emulsion 2 breaking effect depending on the characteristics of the emulsion. 3 4 Recent evidence discovered through experiments and modeling with heavy oils 5 (~20°API) suggests that hydrate equilibrium temperatures are reduced as water 6 cut increases. The term "hydrate equilibrium temperature" means the 7 temperature at which hydrates will readily form for a given composition of a 8 hydrocarbon containing fluid at a particular pressure and flow rate. The effect 9 of increasing water cut to lower hydrate equilibrium temperature can be found 10 in most hydrocarbon systems and is unique for each particular composition of 11 hydrocarbon containing fluid. For example, compositions may contain mostly 12 natural gas or else predominantly heavy oils. The effect is more pronounced 13 for heavy oils which tend to have low GORs (gas-to-oil ratio) and low bubble 14 points. 15 16 FIG. 1 shows the thermodynamic effect of water cut and brine salinity on the 17 hydrate stability region of a heavy oil (~20°API). In this example, increasing the 18 water cut (no salt present) from 10% to 75% reduces hydrate equilibrium 19 temperature at pressures above the bubble point by approximately 2.5°F; 20 increasing the water cut from 75% to 85% reduces the hydrate equilibrium 21 temperature by another 2.2°F. 22 23 Also, illustrated is the enhanced thermodynamic effect achieved by adding 24 brine instead of fresh water to lower the thermal equilibrium temperature. For 25 the heavy oil, increasing the water cut from 10% to 75% by adding brine with 26 7 weight % NaCl, as opposed to water with no salt, reduces hydrate equilibrium 27 temperature above the bubble point by 7°F compared to 2.5°F when adding 28 fresh water only. Adding brine with 15 weight % NaCl reduces the hydrate 29 equilibrium temperature above the bubble point by 15°F compared to the 30 10% water cut, fresh water case. 31 32 FIG. 2 shows a general change in viscosity of emulsions as a function of water 33 cut. As water cut is increased, a water in oil emulsion can be converted to an

1 oil in water emulsion. The graph shows that viscosity of a water in oil emulsion 2 is usually considerably higher than that of an oil in water emulsion at high water cuts (> than 70% water cut). This is especially pronounced in case of heavy oil 3 4 systems. At water cuts as high as 90%, viscosity is close to that of water. 5 6 In addition to the above thermodynamic effect, it is anticipated that by having an 7 excess of the water phase relative to the hydrocarbon phase in these high 8 water fraction systems, any hydrate formation reaction would be self limiting as 9 hydrate forming components (lighter hydrocarbons) in the flow stream are 10 exhausted. The result is expected to be an oil and hydrate in water slurry. 11 Within certain operating conditions of fluid flow velocity, system geometry, 12 water cut, and temperature and pressure the oil and hydrate in water slurry 13 should remain flowable. 14 15 As already mentioned, brine also enhances the thermodynamic effect on 16 hydrate stability produced by adding water to the system. Water also improves 17 heat retention thereby improving thermal performance of the system which 18 might be helpful for mitigating certain flow assurance issues. Switching to 19 water or high salinity brine injection as the hydrate inhibition strategy is also expected to reduce chemical inhibitor presence in water and the oil phase. 20 21 This will have significant benefits for topside water clean up and should result in 22 reduced penalties imposed on an operator by downstream refineries due to the 23 elimination of methanol from crude oil. Therefore, the proposed strategy is also 24 a more environmentally friendly hydrate inhibition strategy as compared to the 25 current thermodynamic and/or LDHI inhibitor injection strategy since storage. handling, and processing of flammable (methanol), potentially toxic 26 27 (anti-agglomerant LDHIs) chemicals can be eliminated from offshore 28 operations. 29 30 FIG. 3 illustrates a first exemplary embodiment of a hydrate blockage inhibition 31 system 20 which is constructed in accordance with the present invention. An 32

well bore 30 is located in a sub sea formation 32. Perforations 34 in well bore

offshore platform 22 is located in a sea 24 disposed above a sea floor 26. A

- 1 30 allow hydrocarbon containing fluids to be extracted from formation 32.
- 2 Located atop well bore 30 is a sub sea tree 36. Tree 36 passes a hydrocarbon
- 3 containing fluid from well bore 30 to a production flow line or pipeline 40. A sub
- 4 sea manifold 42 is disposed intermediate tree 36 and platform 22.

5

- 6 Platform 22 supports a separator 44 which separates water from the
- 7 hydrocarbon containing fluid received from flow line 40. The separated water
- 8 may be disposed of in conventional fashions such as dumping the water into
- 9 sea 24 after being cleaned to an environmentally acceptable quality.
- Alternatively, a substantial portion of the separated water or brine solution may
- be directed to a water injection flow line 46 which supplies water to be added to
- the hydrocarbon containing fluid received from well bore 30. In this instance,
- the added water is injected into a port (not shown) plumbed into tree 36.
- 14 Separated oil exits from separator 44 through an oil discharge line 48.
- 15 Although, not shown, a separate gas discharge line may also be employed
- when substantial amounts of gas are produced and are separated by separator
- 17 44.

18

- 19 A meter 50 measures and controls the quantity of water which is being passed
- from separator 44 to a pump 52. Pump 52 is used to increase pressure in the
- 21 water passing through water injection conduit 46 and which is injected into the
- 22 produced hydrocarbons from well bore 30. Salt may also be added to water
- 23 injection flow line 46 from a salt dispenser 53, preferably as a brine such as a
- sodium chloride in water solution. In this exemplary embodiment, the water is
- injected into tree 36. A water conduit 54 connects separator 44 and pump 52.
- 26 A water discharge conduit 56 is used to discharge surplus separated water
- 27 which is not to be reinjected to enhance the water cut of the produced
- 28 hydrocarbon containing fluid from well bore 30.

- 30 The produced hydrocarbon containing fluid from well bore 30 typically arrives at
- 31 tree 36 from well bore 30 at a particular pressure and at a temperature which is
- 32 significantly above the temperature suitable for hydrate formation. However, as
- 33 the produced fluid travels to sub sea manifold 42 and up production flow line

1 40, the cold sea waters surrounding flow line 40 may cool the produced 2 hydrocarbon containing fluid sufficiently that hydrate formation blockage may 3 be a significant possibility. That is, the production hydrocarbon containing fluids 4 may enter into the hydrate stability region for the particular composition of oil, gas, water, and other constituents of the produced fluids from well bore 30. 5 6 7 In operation, the amount of water/brine solution added to the produced 8 hydrocarbon containing fluid is dependent on the desired characteristics of the 9 water cut enhanced hydrocarbon containing fluid. For example, if the produced 10 hydrocarbon containing fluid from well bore 30 is at a low water cut, i.e., the 11 produced fluid is an oil emulsion containing water or has a hydrocarbon 12 continuous phase, then sufficient water/brine solution may be added to invert 13 the fluid into a water continuous, water cut enhanced hydrocarbon containing 14 fluid. This addition of water may be sufficient to drop the hydrate equilibrium 15 temperature 2.5°F, 5.0°F, 10°F or even 15°F, depending on how much water 16 and salt is added to the production fluids being injected into tree 36. Also, it 17 may be permissible to allow hydrate formation to readily occur if sufficient water 18 and salt are added to maintain the water cut enhanced production fluid in a 19 slurry state where individual hydrate particles are suspended in a water 20 continuous fluid. Accordingly, blockages formed by hydrates will be avoided in 21 production pipeline 40 which might otherwise occur absent the addition of the 22 water and/or brine to the produced fluids from well bore 30. 23 24 FIG. 4 shows a second exemplary embodiment of a system 120 which is similar 25 to that of the first embodiment shown in FIG. 1. Like components of the system 26 have been given the same reference numerals as in the first embodiment. In 27 this instance, the added water/salt is added downstream of the tree 36 with 28 injection occurring into sub sea manifold 42. 29 30 FIG. 5 shows a third embodiment of a system 220 wherein water/salt is injected downstream of tree 36 and sub sea manifold 42 directly into the production 31 32 pipeline at the base of a riser. The added water/salt should be injected into

production pipeline sufficiently upstream of where the cold sea water could

1 potentially drop the temperature of the production fluid to where hydrate phase 2 stability conditions may exist. Accordingly, the beneficial effects provided by 3 the introduction of added water and salt should be obtained before hydrate 4 formation blockage can occur. 5 6 FIGS. 6 and 7 show respective systems 320 and 420 wherein a submersible 7 pump 60 gathers sea water and adds the extra water to production fluids to 8 inhibit hydrate formation blockage. In system 320, the extra water is added to 9 tree 36. In system 420, the extra water is added into the sub sea manifold 42. 10 The advantage of using these systems 320 and 420 is that no lengthy water 11 injection flow line 46 need be run from platform 22 to sea floor 26. A 12 disadvantage is that additional amounts of water separated by separator 44 13 must be disposed because no water is reinjected into flow line 40. 14 15 FIG. 8 shows a system 520 wherein fresh water is injected into the production 16 flow line 40. Production fluids from well bore 30 are collected by sub sea 17 manifold 42. In this exemplary embodiment, a water well 62 is drilled into the sub sea formation 64 to provide a source of water. A well head 66 controls flow 18 19 from well 62. Preferably, the source of water is fresh water having little brine. 20 The water then can be added to the production fluid anywhere from 21 downstream of the production zone, i.e. where perforations 34 are located to 22 just upstream of where there is a significant potential for hydrate formation 23 blockage to occur. In this particular exemplary embodiment, the added water is 24 plumbed into sub sea manifold 42. Although not shown, a subset salt 25 dispenser could also be used in embodiments 320, 420 and 520 if so desired to 26 enhance the salinity of the water cut enhanced hydrocarbon containing fluids. 27 28 In a manner similar to that described above, the present invention could be 29 used to add water to hydrocarbon containing fluids flowing in pipelines on land 30 or elsewhere where hydrate formation blockage is a concern. For example, the 31 pipeline may be operating in a cold and harsh environment such as in Alaska or 32 Canada where plugging of pipelines and other conduits with hydrate formations 33 is problematic.

1 In summary, this invention calls for multiphase production of crude oil and 2 natural gas at high water cuts, possibly adding water/brine to forcibly push a 3 flow system to higher water cuts. It is expected this strategy will allow 4 operators to address multiple flow assurance issues (hydrate inhibition, 5 emulsion viscosity/stability, system thermal performance, and system hydraulic 6 performance) through a simple, cost-effective, environmentally friendly strategy. 7 8 While in the foregoing specification this invention has been described in relation 9 to certain preferred embodiments thereof, and many details have been set forth 10 for purpose of illustration, it will be apparent to those skilled in the art that the invention is susceptible to alteration and that certain other details described 11 12 herein can vary considerably without departing from the basic principles of the

13

invention.
